Department I - C Plus Plus

Modern and Lucid C++ for Professional Programmers

Week 13 - Dynamic Polymorphism

Prof. Peter Sommerlad / Thomas Corbat Rapperswil, 11.12.2018 HS2018

Recap Week 12

```
Template declaration for Iter

template <typename Iter>
Sack(Iter begin, Iter end) -> Sack<typename std::iterator_traits<Iter>::value_type>;

Constructor signature

Deduced template instance
```

Test for deducing template argument from iterator works

```
void testDeductionForIterators() {
  std::vector values{3, 1, 4, 1, 5, 9, 2, 6};
  Sack aSack(begin(values), end(values));
  ASSERT_EQUAL(values.size(), aSack.size());
}
```

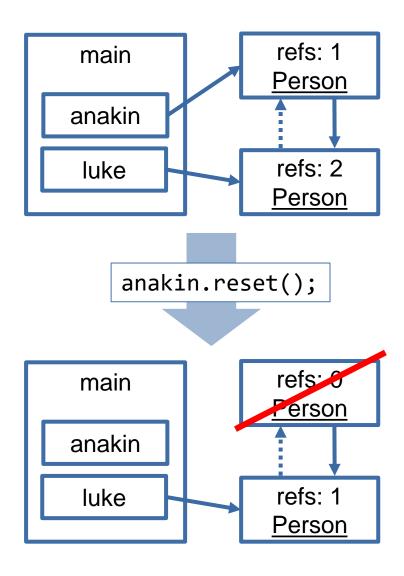

```
std::unique_ptr<X> factory(int i) {
  return std::make_unique<X>(i);
}
```

- std::unique_ptr<T> obtained with std::make_unique<T>()
- std::shared_ptr<T> obtained with std::make_shared<T>()
- std::make_unique<T>() and std::make_shared<T>() are factory functions
- With these smart pointers you don't have to call delete ptr; yourself
- Still: Always prefer storing a value locally as value-type variable (stack-based or member)

• The std::shared ptr cycles need to be broken

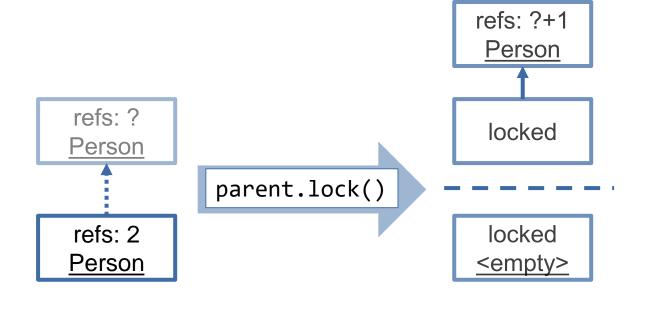

```
struct Person {
   std::shared_ptr<Person> child;
   std::weak_ptr<Person> parent;
};

int main() {
   auto anakin = std::make_shared<Person>();
   auto luke = std::make_shared<Person>();
   anakin->child = luke;
   luke->parent = anakin;
   //...
}
```

- A std::weak_ptr does not know whether the pointee is still alive
 - std::weak_ptr::lock() returns a std::shared_ptr that either points to the alive pointee or is empty

```
struct Person {
  std::shared_ptr<Person> child;
  std::weak ptr<Person> parent;
  void Person::acquireMoney() const {
    auto locked = parent.lock();
    if (locked) {
      begForMoney(*locked);
    } else {
      goToTheBank();
```

Dynamic Polymorphism

Mix-in of functionality from empty base class

- Often with own class as template argument (CRTP) e.g., boost::equality_comparable<T>
- No inherited data members, only added functionality

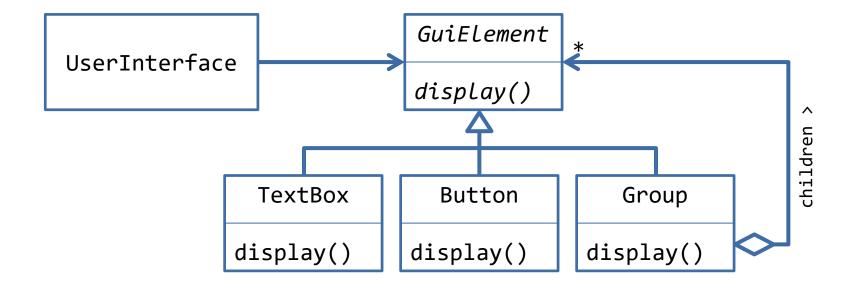

```
struct Date : boost::equality_comparable<Date> {
    //...
};
```

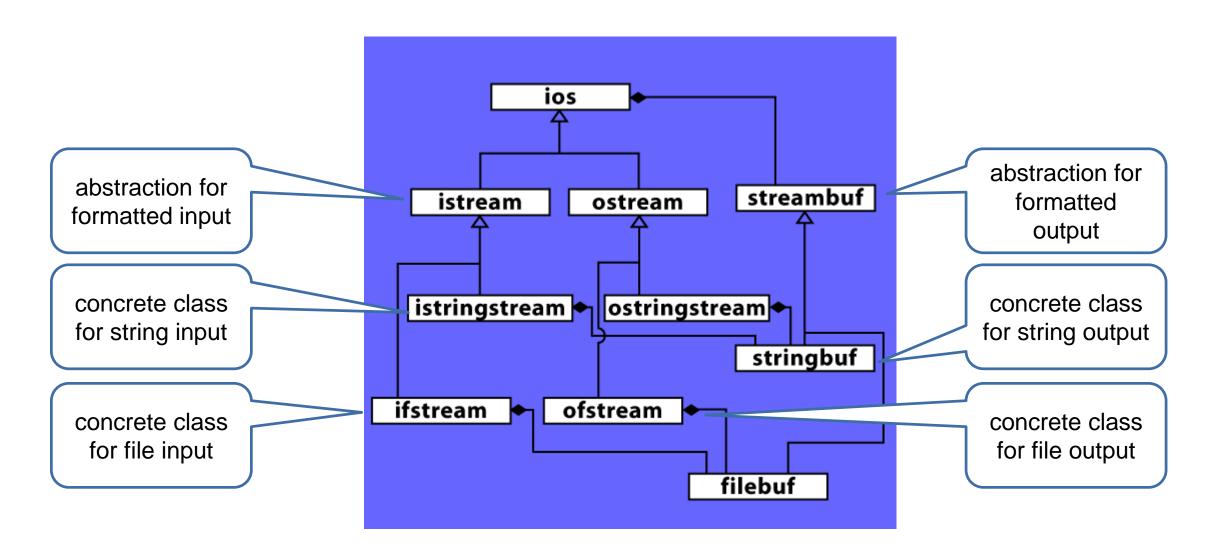

Adapting concrete classes

- No additional own data members
- Convenient for inheriting member functions and constructors

```
template<typename T, typename Compare>
struct indexableSet : std::set<T, Compare> {
    //...
};
```

- Implementing a design pattern with dynamic dispatch
 - e.g., Strategy, Template Method, Composite, Decorator
 - Provide common interface for a variety of dynamically changing or different implementations
 - Exchange functionality at run-time
- Base class/interface class provides a common abstraction that is used by clients

```
class Base {};
class DerivedPrivateBase : Base {};
struct DerivedPublicBase : Base {};
```

- In class definition after class name and a colon put the list of base classes, if any
 - Sequence is important -> sequence of initialization if multiple base classes

```
class Base {};
struct MixIn {};
struct MultipleBases : public Base, private MixIn {};
```

- With interface inheritance, base class must be public
 - Private inheritance is possible, but only useful for mix-in classes that provide friend function
- Private inheritance can be used for some mix-in base classes that only add friend functions, like boost/operators.hpp helper classes
 - Most often, private base classes (with members) are wrong design!

- Base constructors can be explicitly called in the member initializer list
 - If a constructor of a base is omitted its default constructor is called
- You should put base class constructor class before the initialization of members
 - The compiler enforces this rule, even though you can put the list of initializers in wrong order

```
class DerivedWithCtor : public Base1, public Base2 {
  int mvar;
public:
  DerivedWithCtor(int i, int j) :
     Base1{i}, Base2{}, mvar{j} {}
};
```

```
struct Base1 {
  explicit Base1(int value) {
    std::cout << "Base1 with argument " << value << "\n";</pre>
};
struct Base2 {
  Base2() { std::cout << "Base2\n"; }</pre>
};
class DerivedWithCtor : public Base1, public Base2 {
  int mvar;
public:
  DerivedWithCtor(int i, int j)
      : mvar{j}, Base2{}, Base1{mvar} {}
};
int main() {
  DerivedWithCtor dwc{1, 2};
```

- C++' default mechanisms support value classes with copying/moving and deterministic lifetime
- Operator and function overloading and templates allow polymorphic behavior at compile time
 - This is often more efficient and avoids indirection at run-time
- Dynamic polymorphism needs object references or (smart) pointers to work
 - Syntax overhead
 - The base interface must be a good abstraction
 - Copying carries the danger of slicing (an object is only copied partially)
- Implementing design patterns for run-time flexibility: i.e., Strategy, Composite, Decorator
 - Client code uses abstract interface and gets parameterized/called with reference to concrete instance
- But: if run-time flexibility is not required, templates can implement many patterns with compiletime flexibility as well

- If a function is reimplemented in a derived class it shadows its counterpart in the base class
- However, if accessed through a declared base object, the shadowing function is ignored
- The following example prints: Hi, I'm Base

```
struct Base {
  void sayHello() const {
    std::cout << "Hi, I'm Base\n";
  }
};

struct Derived : Base {
  void sayHello() const {
    std::cout << "Hi, I'm Derived\n";
  }
};</pre>
```

```
void greet(Base const & base) {
  base.sayHello();
}
int main() {
  Derived derived{};
  greet(derived);
}
```

- Dynamic polymorphism requires base classes with virtual member functions
 - virtual member functions are bound dynamically
- The following example prints: Hi, I'm Derived

```
struct Base {
  virtual void sayHello() const {
    std::cout << "Hi, I'm Base\n";
  }
};

struct Derived : Base {
  virtual void sayHello() const {
    std::cout << "Hi, I'm Derived\n";
  }
};</pre>
```

```
void greet(Base const & base) {
  base.sayHello();
}
int main() {
  Derived derived{};
  greet(derived);
}
```

- virtual is inherited and can be omitted in the derived class
- It is possible to mark an overriding function with override
 - Similar to the Java annotation @Override the compiler will produce an error if the annotated function does not override a member function in a base class

```
struct Base {
  virtual void sayHello() const {
    std::cout << "Hi, I'm Base\n";
  }
};

struct Derived : Base {
  void sayHello() const override {
    std::cout << "Hi, I'm Derived\n";
  }
};</pre>
```

```
void greet(Base const & base) {
  base.sayHello();
}
int main() {
  Derived derived{};
  greet(derived);
}
```

- To override a virtual function in the base class the signature must be the same
- Constness of the member function belongs to the signature

```
struct Base {
 virtual void sayHello() const {
   std::cout << "Hi, I'm Base\n";</pre>
struct Derived : Base {
 void sayHello() override { /
   std::cout << "Hi, I'm Derived\n";</pre>
void sayHello(std::string name) const override {
   std::cout << "Hi " << name << ", I'm OtherDerived\n";</pre>
```

Value Object

Class type determines function, regardless of virtual

```
struct Base {
  virtual void sayHello() const;
};
struct Derived : Base {
  void sayHello() const;
};
void greet(Base base) {
  //always calls Base::sayHello
  base.sayHello();
```

Reference

 Virtual member of derived class called through base class reference

```
struct Base {
  virtual void sayHello() const;
};
struct Derived : Base {
  void sayHello() const;
};
void greet(Base const & base) {
  //calls sayHello() of the actual type
  base.sayHello();
```

Smart Pointer

Virtual member of derived class called through smart pointer to base class

```
struct Base {
  virtual void sayHello() const;
struct Derived : Base {
  void sayHello() const;
};
void greet(std::unique_ptr<Base> base) {
  //calls sayHello() of the actual type
  base->sayHello();
```

Dumb Pointer

Virtual member of derived class called through base class pointer

```
struct Base {
  virtual void sayHello() const;
};
struct Derived : Base {
 void sayHello() const;
};
void greet(Base const * base) {
  //calls sayHello() of the actual type
  base->sayHello();
```

```
struct Animal {
  void makeSound() {out << "---\n";}</pre>
  virtual void move() {out << "---\n";}</pre>
  Animal() {out << "animal born\n";}</pre>
  ~Animal() {out << "animal died\n";}
};
struct Bird : Animal {
  virtual void makeSound() {out << "chirp\n";}</pre>
  void move() {out << "fly\n";}</pre>
  Bird() {out << "bird hatched\n";}</pre>
  ~Bird() {out << "bird crashed\n";}
};
struct Hummingbird : Bird {
  void makeSound() {out << "peep\n";}</pre>
  virtual void move() {out << "hum\n";}</pre>
  Hummingbird() {out << "hummingbird hatched\n";}</pre>
  ~Hummingbird() {out << "hummingbird died\n";}
};
```

```
int main() {
 out << "(a)-----\n";
   Hummingbird hummingbird;
   Bird bird = hummingbird;
   Animal & animal = hummingbird;
                       -----\n":
 out << "(b)-----
   hummingbird.makeSound();
   bird.makeSound();
   animal.makeSound();
 out << "(c)-----
                    ----\n";
   hummingbird.move();
   bird.move();
   animal.move();
 out << "(d)-----\n";
```

- What is the output?
- What is bad with this code's design?

- There are no interfaces in C++
- A pure virtual member function makes a class abstract
- To mark a virtual member function as pure virtual it has zero assigned after its signature
 - \blacksquare = 0
 - No implementation needs to be provided for that function

```
struct AbstractBase {
  virtual void doitnow() = 0;
};
```

Abstract classes cannot be instantiated (like in Java)

```
AbstractBase create() {
  return AbstractBase{};
}
```

Classes with virtual members require a virtual Destructor

Otherwise when allocated on the heap with std::make_unique<Derived> and assigned to a std::unique_ptr<Base> only the destructor of Base is called

```
struct Fuel {
  virtual void burn() = 0;
  ~Fuel() { std::cout << "put into trash\n"; }
};
struct Plutonium : Fuel {
  void burn() { std::cout << "split core\n"; }</pre>
  ~Plutonium() { std::cout << "store many years\n"; }
};
int main() {
  std::unique ptr<Fuel> surprise = std::make unique<Plutonium>();
```

Output:
put into trash

Classes with virtual members require a virtual Destructor

Otherwise when allocated on the heap with std::make_unique<Derived> and assigned to a std::unique_ptr<Base> only the destructor of Base is called

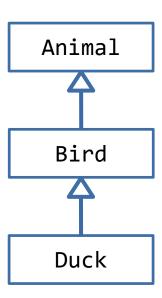

```
struct Fuel {
 virtual void burn() = 0;
 virtual ~Fuel() { std::cout << "put into trash\n"; }</pre>
};
struct Plutonium : Fuel {
 void burn() { std::cout << "split core\n"; }</pre>
  ~Plutonium() { std::cout << "store many years\n"; }
};
int main() {
  std::unique ptr<Fuel> surprise = std::make unique<Plutonium>();
```

Output: store many years put into trash std::shared_ptr memorize the actual type and know which destructor to call

```
struct Fuel {
  virtual void burn() = 0;
  ~Fuel() { std::cout << "put into trash\n"; }
};
struct Plutonium : Fuel {
  void burn() { std::cout << "split core\n"; }</pre>
  ~Plutonium() { std::cout << "store many years\n"; }
};
int main() {
  std::shared_ptr<Fuel> surprise = std::make_shared<Plutonium>();
```

Output: store many years put into trash

- Inheritance introduces a very strong coupling between subclasses and their base class
 - You can hardly change the base class
- API of base class must fit for all subclasses.
 - Very hard to get right
- Conceptual hierarchies are often used as examples but are usually very bad software design, e.g., animal->bird->duck
- Only one standard library part (the oldest) uses inheritance with dynamic polymorphism: iostreams

- Assigning or passing by value a derived class value to a base class variable/parameter incurs
 object slicing
 - Only base class member variables are transferred

```
struct Base {
  int member{};
  explicit Base(int initial) :
     member{initial}{}
 virtual ~Base() = default;
 virtual void modify() { member++; }
 void print(std::ostream & out) const;
};
struct Derived : Base {
 using Base::Base;
 void modify() {
   member += 2;
```

```
void modifyAndPrint(Base base) {
  base.modify();
  base.print(std::cout);
}
int main() {
  Derived derived{25};
  modifyAndPrint(derived);
}
```

Output: 26

- Member functions in derived classes hide base class member with the same name, even if different parameters are used
 - Can be problematic, esp. with const/non-const
- Example: Derived::modify(int) hides Base::modify()

```
struct Base {
  int member{};
  explicit Base(int initial);
  virtual ~Base() = default; nides
  virtual void modify();
};
```

```
struct Derived : Base {
  using Base::Base;
  void modify(int value) {
    member += value;
  }
};
```

```
int main() {
  Derived derived{25};
  derived.modify();
  modifyAndPrint(derived);
}
```

By "using" the base class' member the hidden name(s) become visible

```
using Base::modify;
```

• This enables a call to derived.modify()

```
struct Base {
  int member{};
  explicit Base(int initial);
  virtual ~Base() = default;
  virtual void modify();
};
```

```
struct Derived : Base {
  using Base::Base;
  using Base::modify;
  void modify(int value) {
    member += value;
  }
};
```

```
int main() {
   Derived derived{25};
   derived.modify();
   modifyAndPrint(derived);
}
```

Assignment cannot be implemented properly for virtual inheritance structures

```
struct Book {
  explicit Book(std::vector<Page> pages) :
    pages{pages}{}
 virtual Page currentPage() const = 0;
protected:
  std::vector<Page> pages;
};
struct EBook : Book {
 using Book::Book;
 void openPage(size t pageNumber);
  Page currentPage() const;
private:
  size_t currentPageNumber{1};
};
```

```
void readBook(Book book);
int main() {
   EBook designPatterns{"..."};
   readBook(designPatterns);

EBook refactoring{"..."};
   Book & some = designPatterns;
   some = refactoring;
}
```

The assignment to the reference of the base class overwrites the Base part of the derived object

```
EBook designPatterns{writeEbook(395)};
EBook refactoring{writeEbook(430)};
refactoring.openPage(400);
Book & some = refactoring;
some = designPatterns;
readPage(some.currentPage());
```

You can declare the copy-operations as deleted

```
struct Book {
 //...
  Book & operator=(Book const & other) = delete;
  Book(Book const & other) = delete;
};
struct EBook : Book {
  //...
 EBook(EBook const & other) :
    Book{pages},
    currentPageNumber{other.currentPageNumber}{}
  EBook & operator=(EBook const & other) {
    pages = other.pages;
    currentPageNumber = other.currentPageNumber;
    return *this;
```

```
void readBook(Book book);

int main() {
    EBook designPatterns{"..."};
    readBook(designPatterns);

EBook refactoring{"..."};
    Book & some = designPatterns;
    some = refactoring;
    EBook copy = designPatterns;
    copy = refactoring;
}
```

- You should only apply inheritance and virtual member functions if you know what you do
- Do not (like the IDE) create classes with virtual members by default
- If you design base classes with polymorphic behavior, understand the common abstraction that they represent
 - Do not provide too many members or too few
 - Extract from existing class(es) the base after you see the commonality arise

Follow the Liskov Substitution Principle

- Base class states must be valid for subclasses.
- Do not break invariants of the base class.
- Invariant signature: Member functions in subclasses must accept the same argument types as the base class (C++)
- Covariant return type: Return values must be inside the base class member function's range
- Don't change semantics unexpectedly

Three use cases:

- Inherit features from empty mix-in classes
- Adapt features of a base class with a data-less subclass
- Dynamic polymorphism
- Beware of unwanted member hiding
- Avoid object slicing
- Mark Destructors virtual if you have any other virtual member function
